Background and Aims:

Incorporation of an insulin sensor may help to improve performance of future AP algorithms by reducing severe hypoglycemic events. Optimal insulin measurement intervals were identified for a feedback-based threshold suspend safety-layer.

Method:

Personalized Kalman filter-estimated plasma insulin concentration (EPIC) measurements were used to supplement a zone model predictive control algorithm. Insulin delivery was suspended when both CGM was <140 mg/dL and EPIC values were greater than a personalized threshold based on fasting basal insulin concentrations. EPIC measurements occurred at 5-, 30-, 60-, 120-, and 180-minute intervals. Using the UVA/Padova Simulator, the controller was evaluated across ten *in-silico* subjects for three 8-hour, 50-gram carbohydrate scenarios: 1) sixty-minute exercise, induced via increasing glucose uptake rates, one hour after an announced meal, 2) meal size overestimation by 35% with carbohydrate ratio underestimated by 25%, and 3) announced meal (baseline).

Results:

Implementing the EPIC safety-layer, the mean percent time below 70 mg/dL decreased: from $8.09 \pm 9.08\%$ to $2.47 \pm 5.24\%$ for 5-minute, $7.07 \pm 7.75\%$ for 30-minute, $7.57 \pm 8.28\%$ for 60-minute, and $7.59 \pm 8.26\%$ for 120- through 180-minute intervals (scenario 1); from $5.07 \pm 5.33\%$ to $0.00 \pm 0.00\%$ for 5- through 30-minute, $0.87 \pm 2.76\%$ for 60-minute, $2.12 \pm 4.65\%$ for 120-minute, and $3.16 \pm 5.38\%$ for 180-minute intervals (scenario 2); and from $0.69 \pm 2.17\%$ to $0.00 \pm 0.00\%$ for 30- through 120-minute, while remaining at $0.69 \pm 2.17\%$ for 180-minute intervals (scenario 3). Infrequent measurements of 30- to 120- minutes resulted in slight performance degradation with increasing sample time.

Table 1: Glycemic control without insulin information compared with various EPIC safety-layer measurement intervals. Data are shown as mean \pm standard deviation. *Indicates a p-value < 0.05 .

1 Meal Scenario (8 hours)	EPIC Measurement Interval (min)	Time above 180 mg/dL (%)	p-value	Time between 70-180 mg/dL (%)	p-value	Time below 70 mg/dL (%)	p-value	Time below 63 mg/dL (%)	p-value	Time below 54 mg/dL (%)	p-value

Conclusion:

The EPIC safety-layer *in-silico* prevented severe hypoglycemia during challenging scenarios without significant rebound hyperglycemia. Future insulin sensors could potentially be designed utilizing 30- to 120-minute measurement intervals.
